

Python Lambda

A lambda function is a small anonymous function.

A lambda function can take any number of arguments, but can only have one expression.

Syntax

lambda arguments : expression

The expression is executed and the result is returned:

Example

Add 10 to argument *a*, and return the result:

```
x = lambda a : a + 10
print(x(5))
```

Lambda functions can take any number of arguments:

Example

Multiply argument *a* with argument *b* and return the result:

```
x = lambda a, b : a * b
print(x(5, 6))
```

Example

Summarize argument *a*, *b*, and *c* and return the result:

```
x = lambda a, b, c : a + b + c
print(x(5, 6, 2))
```

Why Use Lambda Functions?

The power of lambda is better shown when you use them as an anonymous function inside another function.

Say you have a function definition that takes one argument, and that argument will be multiplied with an unknown number:

```
def myfunc(n):  
    return lambda a : a * n
```

Use that function definition to make a function that always doubles the number you send in:

Example

```
def myfunc(n):  
    return lambda a : a * n
```

```
mydoubler = myfunc(2)
```

```
print(mydoubler(11))
```

Or, use the same function definition to make a function that always *triples* the number you send in:

Example

```
def myfunc(n):  
    return lambda a : a * n
```

```
mytripler = myfunc(3)
```

```
print(mytripler(11))
```

Or, use the same function definition to make both functions, in the same program:

Example

```
def myfunc(n):  
    return lambda a : a * n
```

```
mydoubler = myfunc(2)
```

```
mytripler = myfunc(3)
```

```
print(mydoubler(11))
```

```
print(mytripler(11))
```
